### Computer Systems Organization (CS2.201)

LECTURE 8 & 9 & 10 - PROCESSOR ARCHITECTURE DESIGN: PIPELINING (SECTION 4.4 TILL 4.5.5)

Deepak Gangadharan Computer Systems Group (CSG), IIIT Hyderabad

Slide Contents: Adapted from slides by Randal Bryant

### Overview

### **General Principles of Pipelining**

- Goal
- Difficulties

### Creating a Pipelined Y86-64 Processor

- Rearranging SEQ
- Inserting pipeline registers
- Problems with data and control hazards

# Real-World Pipelines: Car Washes

### Sequential

**Pipelined** 

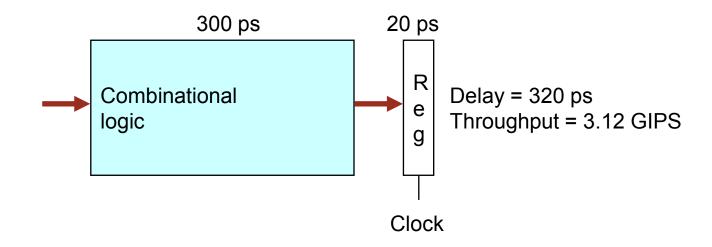

### Parallel

### Idea

- Divide process into independent stages
- Move objects through stages in sequence
- At any given times, multiple objects being processed

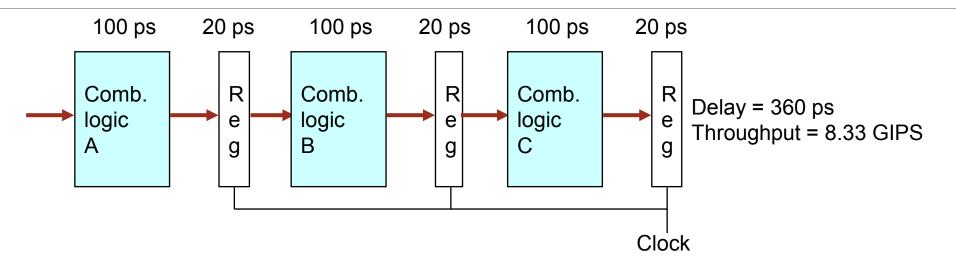

## Computational Example

### System

- Computation requires total of 300 picoseconds
- Additional 20 picoseconds to save result in register
- Must have clock cycle of at least 320 ps

## 3-Way Pipelined Version

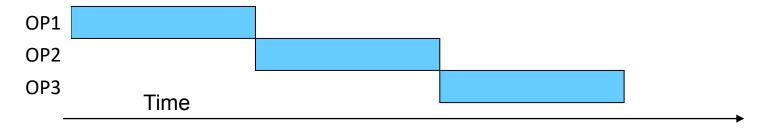

### System

- Divide combinational logic into 3 blocks of 100 ps each
- Can begin new operation as soon as previous one passes through stage A.
  - Begin new operation every 120 ps
- Overall latency increases
  - 360 ps from start to finish

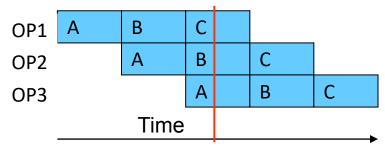

# Pipeline Diagrams

### Unpipelined

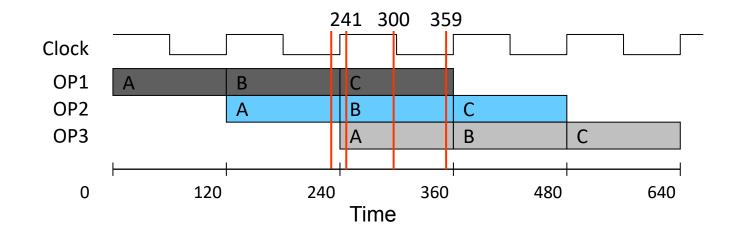

Cannot start new operation until previous one completes

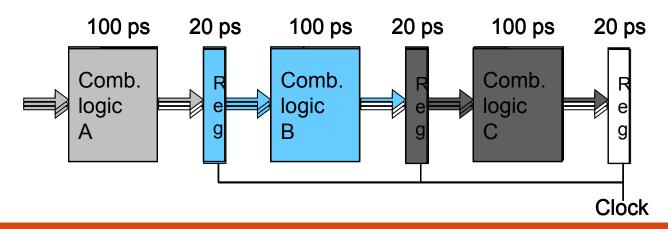

### 3-Way Pipelined

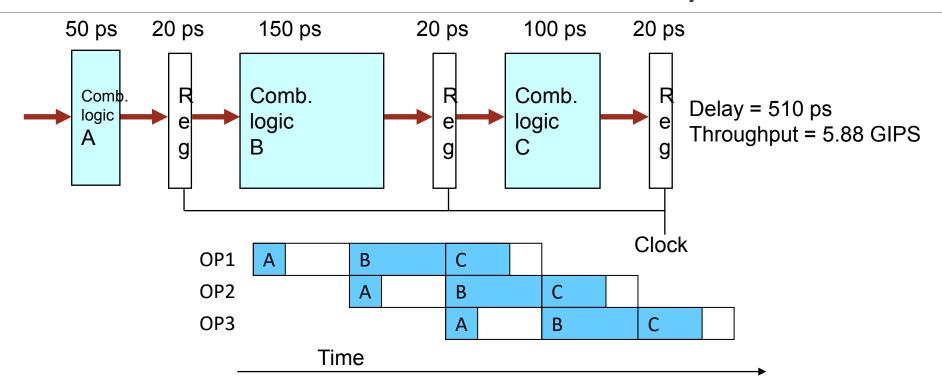

Up to 3 operations in process simultaneously

# Operating a Pipeline

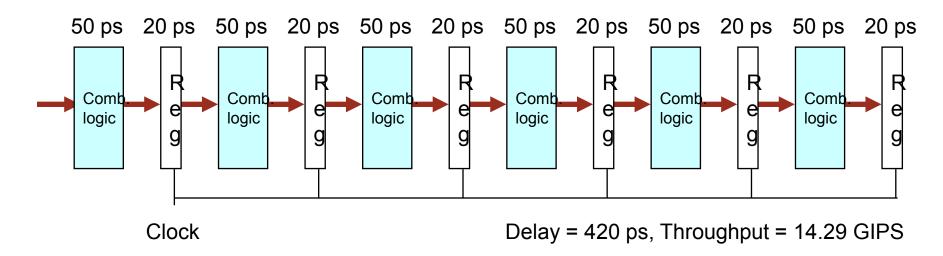

## Limitations: Nonuniform Delays

- Throughput limited by slowest stage
- Other stages sit idle for much of the time
- Challenging to partition system into balanced stages

# Limitations: Register Overhead

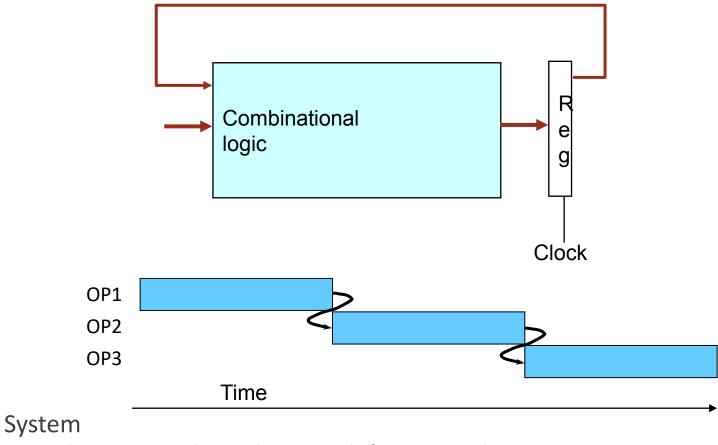

- As try to deepen pipeline, overhead of loading registers becomes more significant
- Percentage of clock cycle spent loading register:

1-stage pipeline: 6.25%3-stage pipeline: 16.67%6-stage pipeline: 28.57%

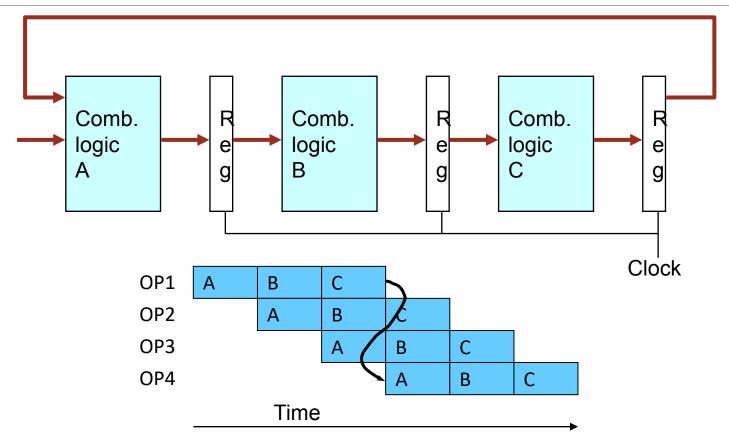

High speeds of modern processor designs obtained through very deep pipelining

# Data Dependencies

• Each operation depends on result from preceding one

### Data Hazards

- Result does not feed back around in time for next operation
- Pipelining has changed behavior of system

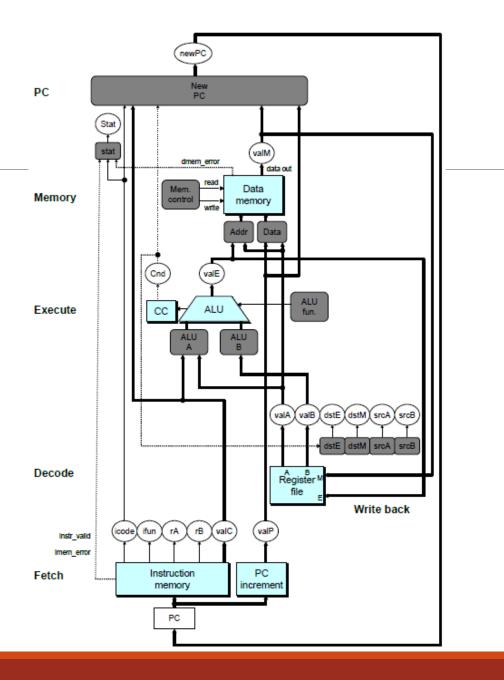

## Data Dependencies in Processors

```
1 irmovq $50, %rax
2 addq %rax, %rbx
3 mrmovq 100(%rbx), %rdx
```

- Result from one instruction used as operand for another
  - Read-after-write (RAW) dependency
- Very common in actual programs
- Must make sure our pipeline handles these properly
  - Get correct results
  - Minimize performance impact

# SEQ Hardware

- Stages occur in sequence
- One operation in process at a time

## SEQ+ Hardware

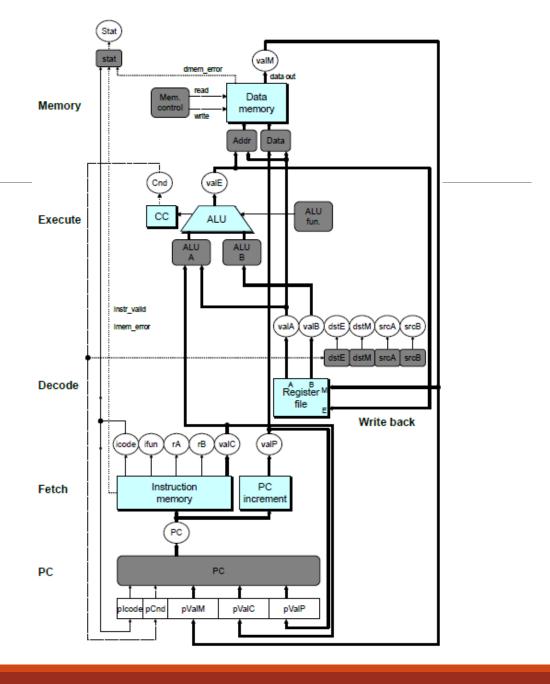

- Still sequential implementation
- Reorder PC stage to put at beginning

### PC Stage

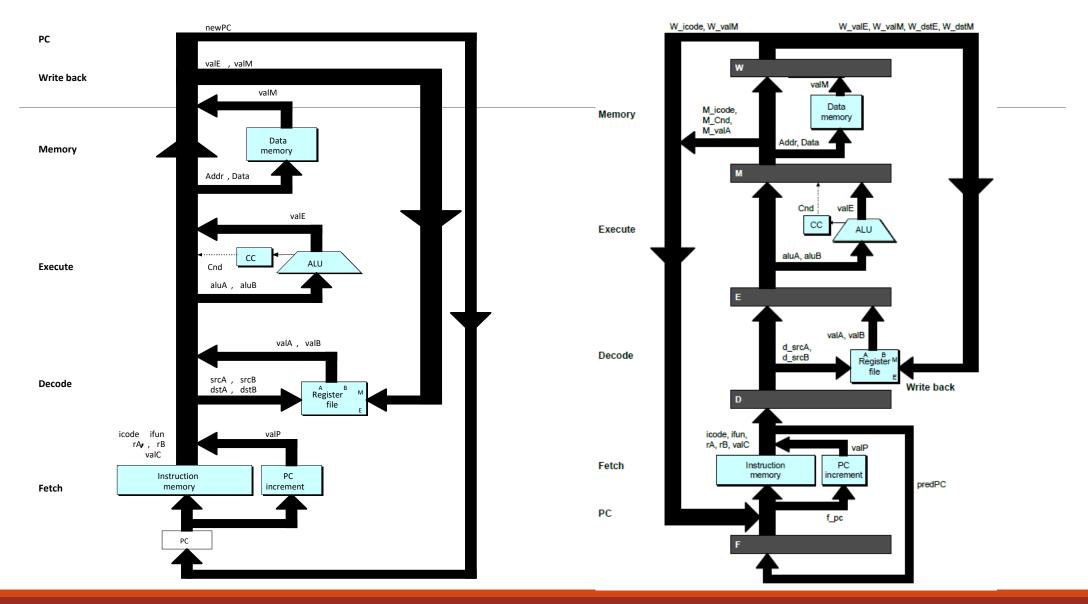

- Task is to select PC for current instruction
- Based on results computed by previous instruction

### **Processor State**

- PC is no longer stored in register
- But, can determine PC based on other stored information

# Adding Pipeline Registers

# Pipeline Stages

### Fetch

- Select current PC
- Read instruction
- Compute incremented PC

### Decode

Read program registers

#### Execute

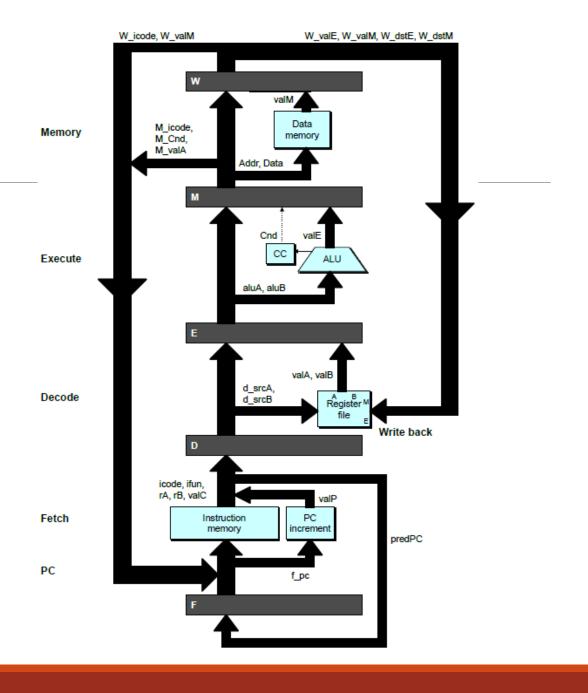

Operate ALU

### Memory

Read or write data memory

### Write Back

Update register file

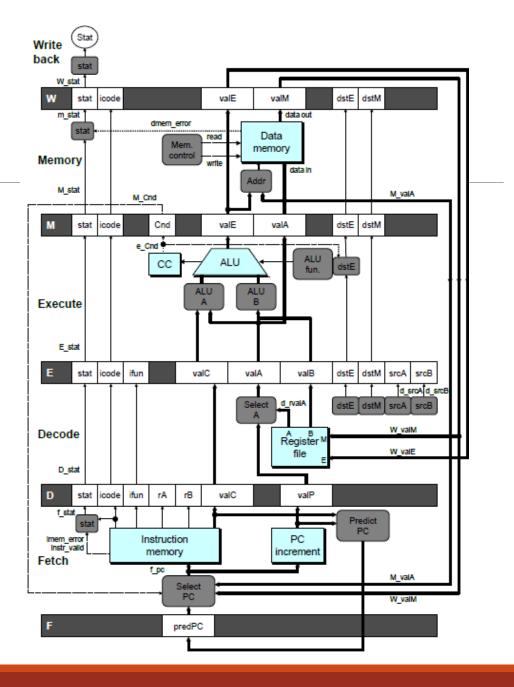

### PIPE- Hardware

 Pipeline registers hold intermediate values from instruction execution

### Forward (Upward) Paths

- Values passed from one stage to next
- Cannot jump past stages
  - e.g., valC passes through decode

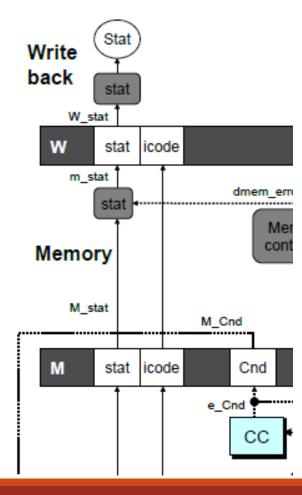

# Signal Naming Conventions

### S\_Field

Value of Field held in stage S pipeline register

### s\_Field

Value of Field computed in stage S

### Feedback Paths

### Predicted PC

Guess value of next PC

### **Branch** information

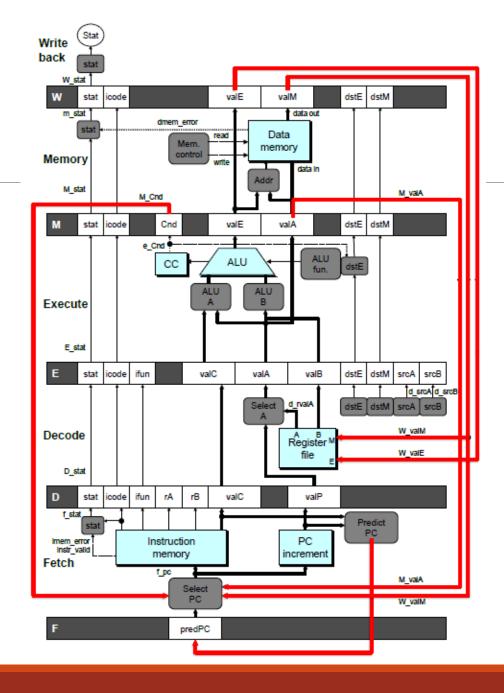

- Jump taken/not-taken
- Fall-through or target address

### Return point

Read from memory

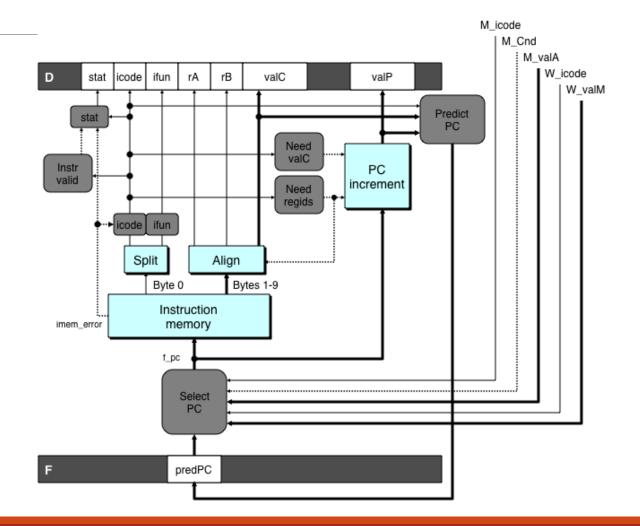

### Register updates

To register file write ports

## Predicting the PC

- Start fetch of new instruction after current one has completed fetch stage
  - Not enough time to reliably determine next instruction
- Guess which instruction will follow
  - Recover if prediction was incorrect

## Our Prediction Strategy

#### Instructions that Don't Transfer Control

- Predict next PC to be valP
- Always reliable

### Call and Unconditional Jumps

- Predict next PC to be valC (destination)
- Always reliable

### **Conditional Jumps**

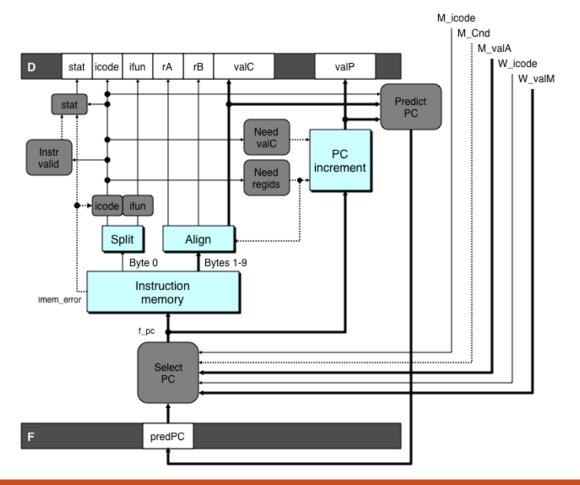

- Predict next PC to be valC (destination)
- Only correct if branch is taken
  - Typically right 60% of time

#### **Return Instruction**

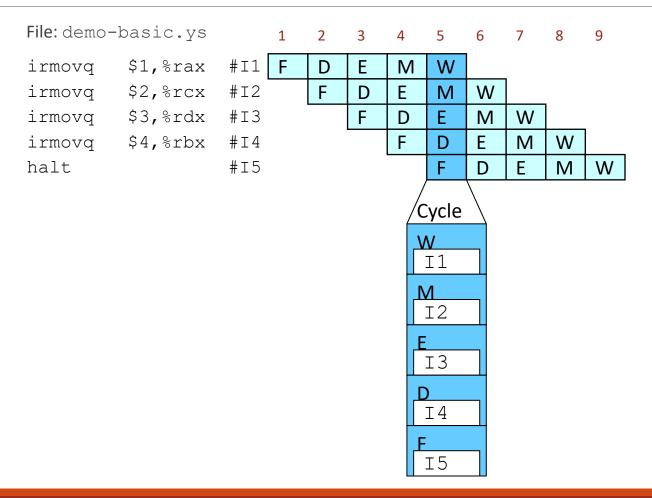

Don't try to predict

## Recovering from PC Misprediction

- Mispredicted Jump
  - Will see branch condition flag once instruction reaches memory stage
  - Can get fall-through PC from valA (value M\_valA)
- Return Instruction
  - Will get return PC when ret reaches write-back stage (W\_valM)

## Pipeline Demonstration

## Data Dependencies: 3 Nop's

```
10
                                                                                             11
# demo-h3.ys
0x000: irmovq $10,% rdx
                                                           W
0x00a: irmovq $3,% rax
                                                           M
0x014: nop
                                                                      W
0x015: nop
                                                                      M
                                                                            W
0x016: nop
                                                                                 W
0x017: addq % rdx, % rax
                                                                                       W
0x019: halt
                                                                                             W
                                                    Cycle 6
                                                       W
                                              R[% rax] \leftarrow 3
                                                                            Cycle 7
                                                                      valA \leftarrow R[ % rdx] = 10
                                                                      valB \leftarrow R[\% rax] = 3
```

## Data Dependencies: 2 Nop's

```
10
# demo-h2.ys
0x000: irmovq $10,% rdx
0x00a: irmovq $3,% rax
                                                        W
0x014: nop
                                                             W
                                                        M

                                        valA ← R[% rdx] = 0
```

valB  $\leftarrow$  R[% rax] = 0

## Branch Misprediction Example

```
demo-j.ys
0 \times 000:
           xorq %rax, %rax
0 \times 0.02:
                                # Not taken
           jne t
0x00b:
           irmovq $1, %rax
                                # Fall through
0 \times 015:
           nop
0 \times 016:
           nop
0 \times 017:
           nop
0 \times 018:
        halt
0x019: t: irmovq $3, %rdx
                                 # Target (Should not execute)
0 \times 023:
           irmovg $4, %rcx  # Should not execute
0x02d:
           irmovq $5, %rdx # Should not execute
```

## Branch Misprediction Trace

Incorrectly execute two instructions at branch target

## Return Example

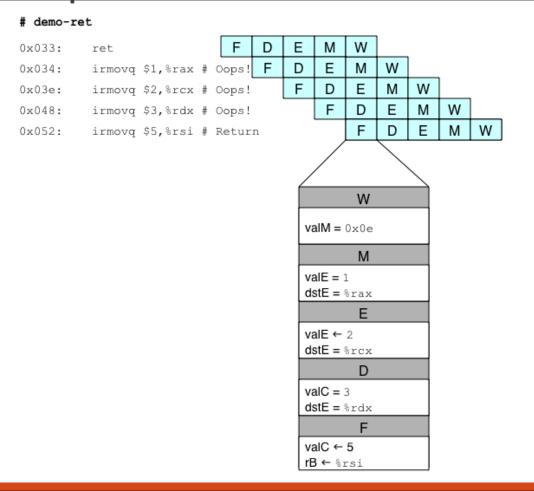

#### demo-ret.ys

```
0 \times 000:
             irmovq Stack,%rsp # Intialize stack pointer
0 \times 0.0 a:
                                 # Avoid hazard on %rsp
          nop
0 \times 0.0 \text{ b}:
          nop
0x00c:
          nop
0x00d:
         call p
                                 # Procedure call
0 \times 016:
        irmova $5,%rsi
                                 # Return point
0 \times 020:
          halt.
0x020: pos 0x20
0x020: p: nop
                                   # procedure
0 \times 021:
          nop
0 \times 022:
         nop
0 \times 0.23:
        ret.
0x024: irmovq $1,%rax # Should not be executed
0x02e: irmovq $2,%rcx # Should not be executed
0x038: irmovq $3,%rdx
                                  # Should not be executed
0 \times 042:
          irmovq $4,%rbx
                                  # Should not be executed
0x100: .pos 0x100
0x100: Stack:
                                  # Initial stack pointer
```

Require lots of nops to avoid data hazards

## Incorrect Return Example

Incorrectly execute 3 instructions following ret

# Stalling for Data Dependencies

```
10 11
# demo-h2.ys
0x000: irmovg $10,%rdx
                                         M
                                             W
0x00a: irmovq $3,%rax
                                                  W
0x014: nop
                                         D
                                                      W
0x015: nop
                                                           W
                                             D
       bubble.
                                                               W
                                                           M
0x016: addq %rdx, %rax
                                             F
                                                  D
                                                                   W
0x018: halt
                                                  F
                                                                        W
                                                           D
                                                                   M
```

- If instruction follows too closely after one that writes register, slow it down
- Hold instruction in decode
- Dynamically inject nop into execute stage

### Stall Condition

### Source Registers

 srcA and srcB of current instruction in decode stage

### **Destination Registers**

- dstE and dstM fields
- Instructions in execute, memory, and writeback stages

### **Special Case**

- Don't stall for register ID 15 (0xF)
  - Indicates absence of register operand
  - Or failed cond. move

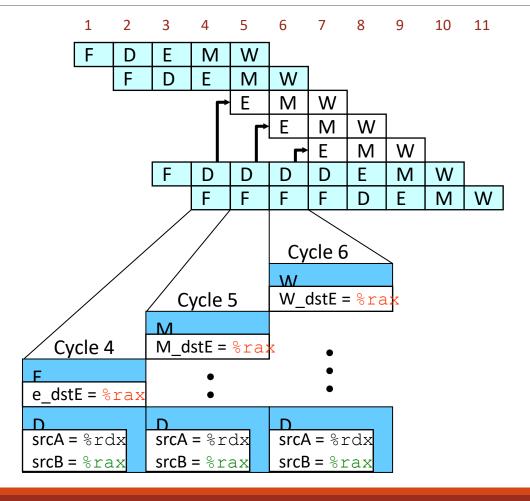

## **Detecting Stall Condition**

```
# demo-h2.ys
                                                               10 11
0x000: irmovq $10,%rdx
                                      Ε
                                             W
                                          M
0x00a: irmovq $3,%rax
                                      D
                                                 W
                                             M
0x014: nop
                                                     M
                                                        W
0x015: nop
                                                            W
       bubble
                                             F
                                                                W
                                                                   W
0x016: addq %rdx,%rax
0x018: halt
                                               Cycle 6
                                            W_dstE = %rax
                                            W valE = 3
                                            srcA = %rdx
```

srcB = %rax

# Stalling X3

0x016: halt

# What Happens When Stalling?

# demo-h0.ys

0x000: irmovq \$10,%rdx

0x00a: irmovq \$3,%rax

0x014: addq %rdx,%rax

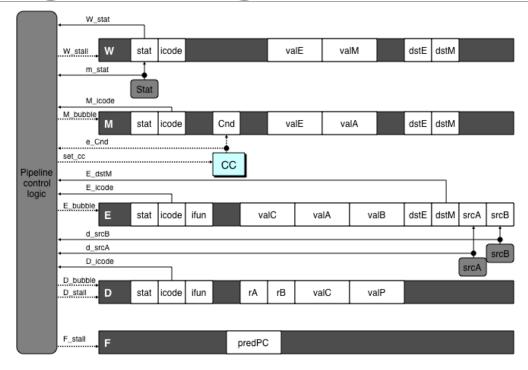

0x016: halt

### Cycle 8

Write Back	bubble
Memory	bubble
Execute	0x014: addq %rdx,%rax
Decode	0x016: halt
Fetch	

- Stalling instruction held back in decode stage
- Following instruction stays in fetch stage
- Bubbles injected into execute stage
  - Like dynamically generated nop's
  - Move through later stages

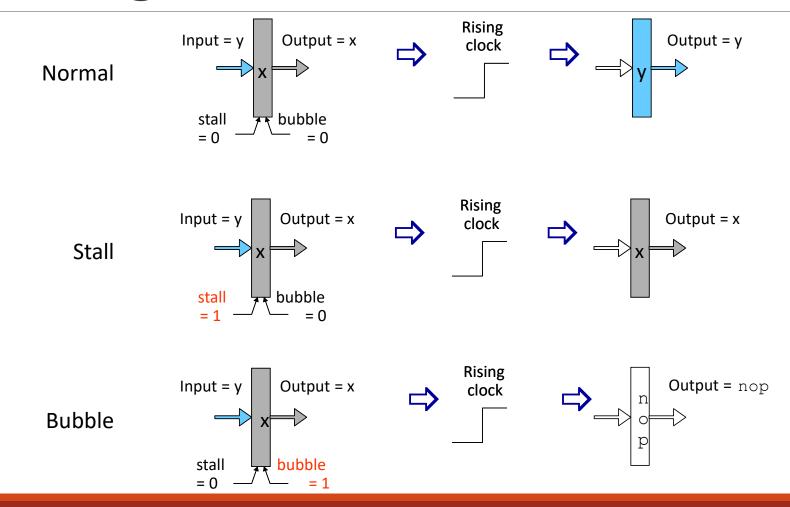

# Implementing Stalling

#### Pipeline Control

- Combinational logic detects stall condition
- Sets mode signals for how pipeline registers should update

# Pipeline Register Modes

## Data Forwarding

#### Naïve Pipeline

- Register isn't written until completion of write-back stage
- Source operands read from register file in decode stage
  - Needs to be in register file at start of stage

#### Observation

Value generated in execute or memory stage

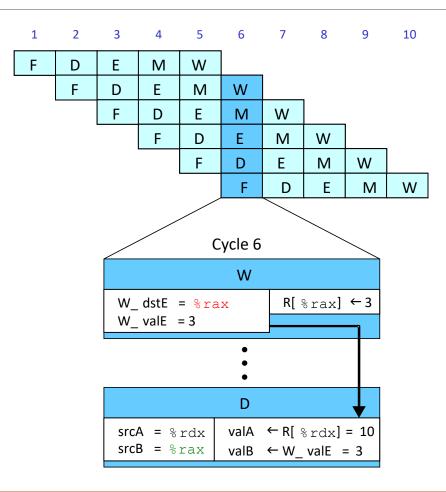

#### Trick

- Pass value directly from generating instruction to decode stage
- Needs to be available at end of decode stage

## Data Forwarding Example

```
# demo-h2.ys
0x000: irmovq$10,% rdx
0x00a: irmovq $3,% rax
0x014: nop
0x015: nop
0x016: addq % rdx,% rax
0x018: halt
```

- irmovq in write-back stage
- Destination value in W pipeline register
- Forward as valB for decode stage

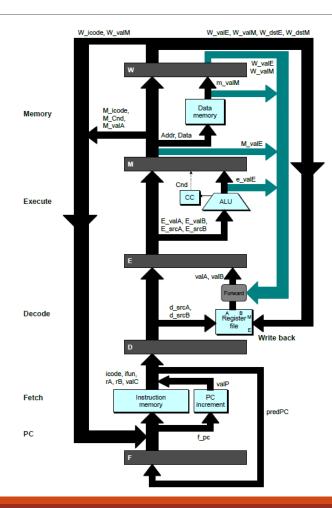

#### Bypass Paths

#### **Decode Stage**

- Forwarding logic selects valA and valB
- Normally from register file
- Forwarding: get valA or valB from later pipeline stage

#### **Forwarding Sources**

- Execute: valE
- Memory: valE, valM
- Write back: valE, valM

# Data Forwarding Example #2

#### # demo-h0.ys

0x000: irmovq \$10,%rdx
0x00a: irmovq \$3,%rax
0x014: addq %rdx,%rax

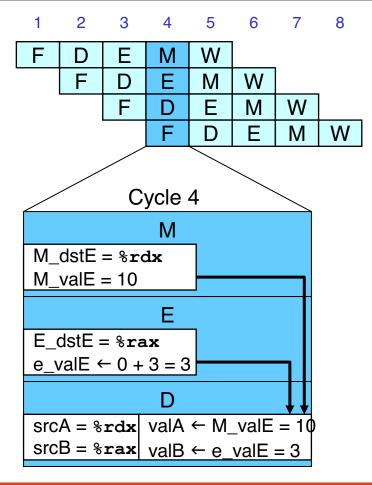

0x016: halt

#### Register %rdx

- Generated by ALU during previous cycle
- Forward from memory as valA

#### Register %rax

- Value just generated by ALU
- Forward from execute as valB

## Forwarding Priority

# demo-priority.ys

0x000: irmovq \$1, %rax

0x00a: irmovq \$2, %rax

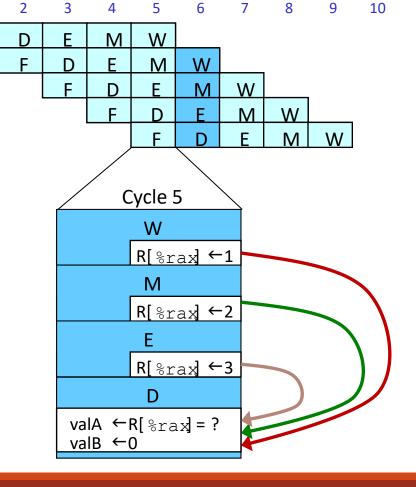

0x014: irmovq \$3, %rax

0x01e: rrmovq %rax, %rdx

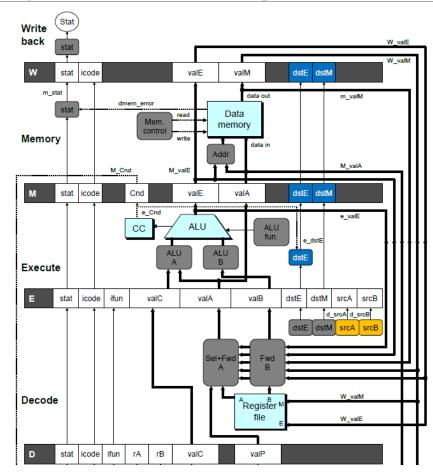

0x020: halt

#### Multiple Forwarding Choices

- Which one should have priority
- Match serial semantics
- Use matching value from earliest pipeline stage

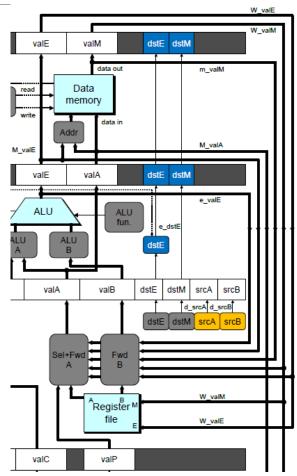

#### Implementing Forwarding

- Add additional feedback paths from E, M, and W pipeline registers into decode stage
- Create logic blocks to select from multiple sources for valA and valB in decode stage

## Implementing Forwarding

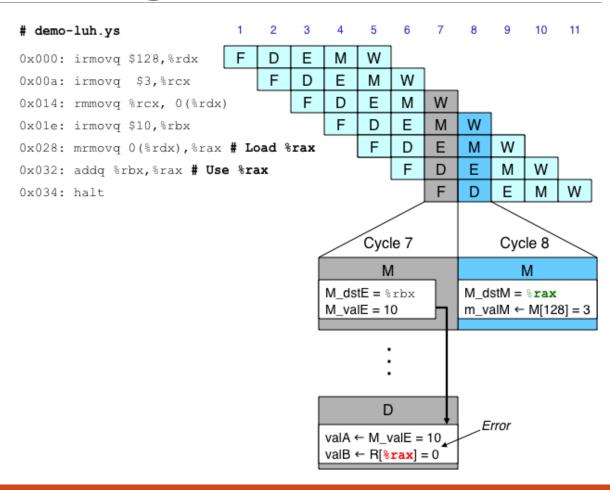

```
## What should be the A value?
int d valA = [
  # Use incremented PC
    D icode in { ICALL, IJXX } : D valP;
  # Forward valE from execute
    d srcA == e dstE : e valE;
 # Forward valM from memory
    d srcA == M dstM : m valM;
  # Forward valE from memory
    d srcA == M dstE : M valE;
  # Forward valM from write back d_srcA
== W dstM : W valM;
  # Forward valE from write back
    d srcA == W dstE : W valE;
  # Use value read from register file
    1: d rvalA; -> implies no dependency
];
```

## Limitation of Forwarding

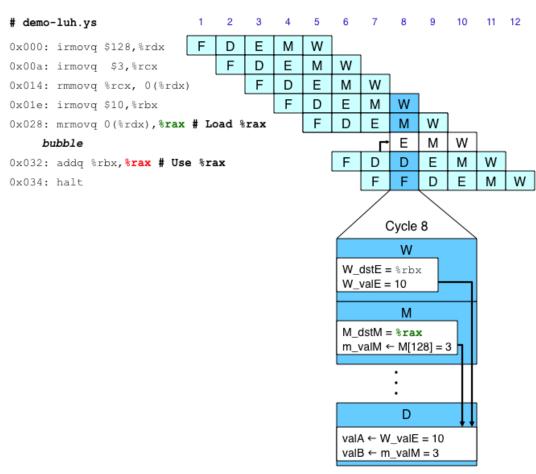

#### Load-use dependency

- Value needed by end of decode stage in cycle 7
- Value read from memory in memory stage of cycle 8

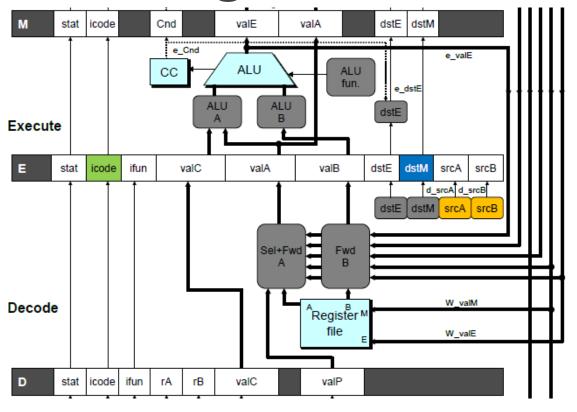

#### Avoiding Load/Use Hazard

- Stall using instruction for one cycle
- Can then pick up loaded value by forwarding from memory stage

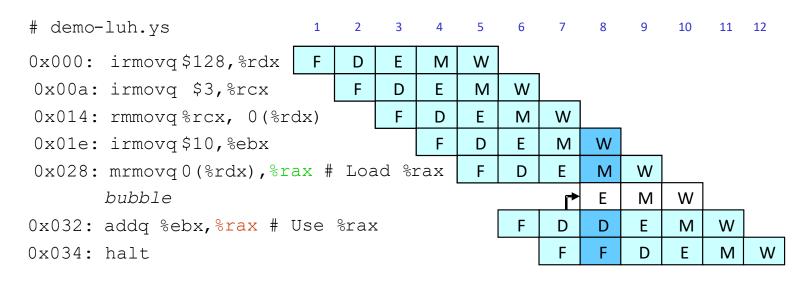

# Detecting Load/Use Hazard

Condition	Trigger
Load/Use Hazard	<pre>E_icode in { IMRMOVQ, IPOPQ } &amp;&amp; E_dstM in { d_srcA, d_srcB }</pre>

#### Control for Load/Use Hazard

- Stall instructions in fetch and decode stages
- Inject bubble into execute stage

Condition	F	D	ш	M	W
Load/Use Hazard	stall	stall	bubble	normal	normal

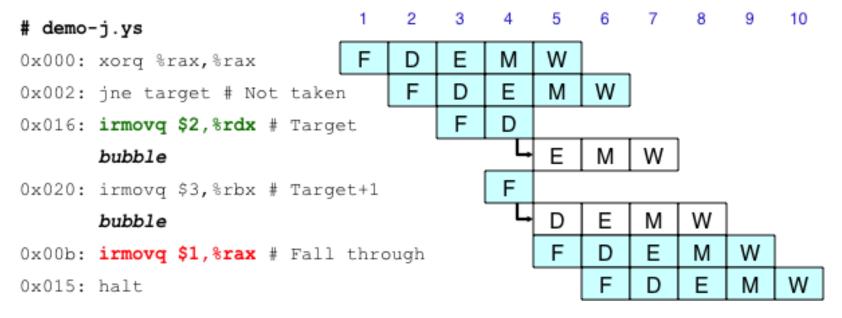

## Branch Misprediction Example

```
0 \times 0000:
       xorq %rax,%rax
0 \times 002:
                            # Not taken
       ine t
0 \times 0.0 \text{ b}:
           irmovq $1, %rax  # Fall through
0 \times 015:
           nop
0 \times 016:
           nop
0 \times 017:
           nop
0 \times 018:
       halt
0x019: t: irmovq $3, %rdx  # Target
0x023: irmovq $4, %rcx # Should not execute
0 \times 02d:
           irmovq $5, %rdx # Should not execute
```

Should only execute first 8 instructions

demo-j.ys

# Handling Misprediction

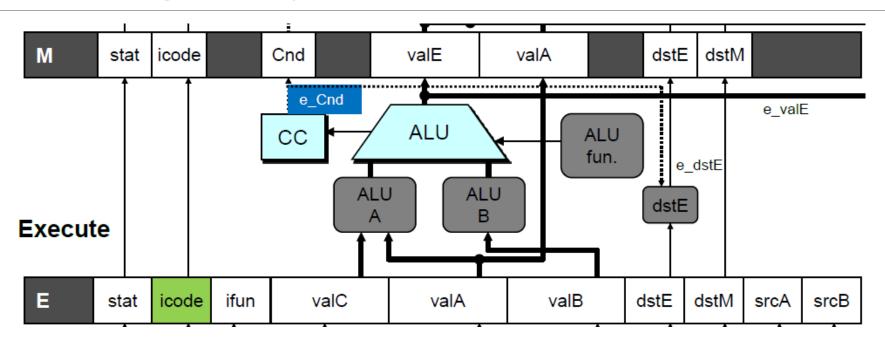

#### Predict branch as taken

Fetch 2 instructions at target

#### Cancel when mispredicted

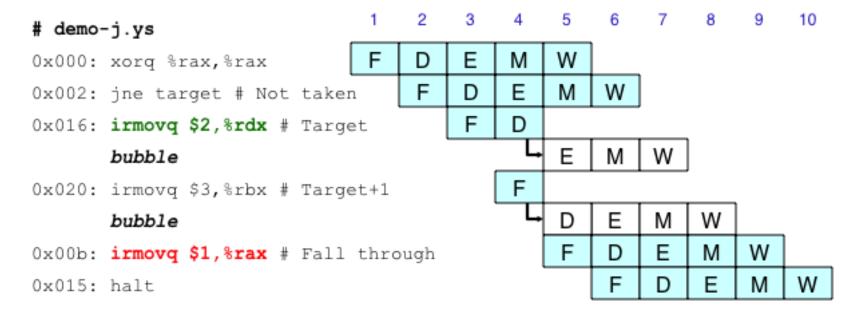

- Detect branch not-taken in execute stage
- On following cycle, replace instructions in execute and decode by bubbles
- No side effects have occurred yet

## Detecting Mispredicted Branch

Condition	Trigger
<b>Mispredicted Branch</b>	E_icode = IJXX & !e_Cnd

## Control for Misprediction

Condition	F	D	E	M	W
<b>Mispredicted Branch</b>	normal	bubble	bubble	normal	normal

## Return Example

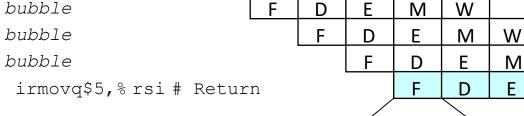

#### demo-retb.ys

```
0 \times 0 0 0 :
      irmovq Stack,%rsp # Intialize stack pointer
                  # Procedure call
0x00a: call p
0 \times 013:
      irmovq $5,%rsi  # Return point
0x01d: halt
0x020: pos 0x20
0x020: p: irmovq $-1,%rdi
                           # procedure
0x02a: ret
0x02b: irmovq $1,%rax # Should not be executed
0x035: irmovq $2,%rcx # Should not be executed
0x03f: irmovq $3,%rdx # Should not be executed
0 \times 049:
      irmovq $4,%rbx
                           # Should not be executed
0x100: .pos 0x100
0x100: Stack:
                           # Stack: Stack pointer
```

Previously executed three additional instructions

#### Correct Return Example

 $0 \times 013$ :

M

W

W

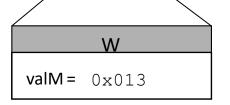

W

Ε

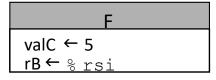

D

As ret passes through pipeline, stall at fetch stage

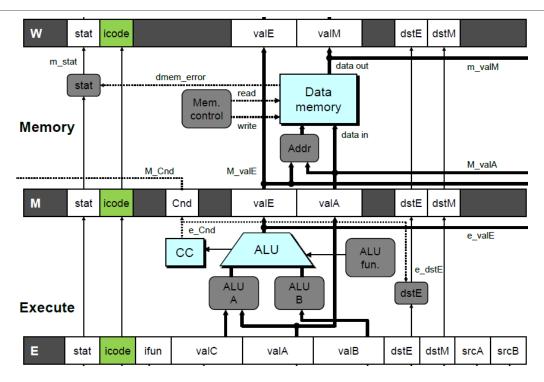

- While in decode, execute, and memory stage
- Inject bubble into decode stage
- Release stall when reach write-back stage

•

# Detecting Return

Condition	Trigger				
Processing ret	<pre>IRET in { D_icode, E_icode, M_icode }</pre>				

#### Control for Return

Condition	F	D	Ш	M	W
Processing ret	stall	bubble	normal	normal	normal

# Initial Version of Pipeline Control

```
bool F stall =
     # Conditions for a load/use hazard
     E icode in { IMRMOVQ, IPOPQ } && E dstM in { d srcA, d srcB } ||
     # Stalling at fetch while ret passes through pipeline
     IRET in { D icode, E icode, M icode };
bool D stall =
     # Conditions for a load/use hazard
     E icode in { IMRMOVQ, IPOPQ } && E dstM in { d srcA, d srcB };
bool D bubble =
     # Mispredicted branch
     (E icode == IJXX && !e Cnd) ||
     # Stalling at fetch while ret passes through pipeline
      IRET in { D icode, E icode, M icode };
bool E bubble =
     # Mispredicted branch
     (E icode == IJXX && !e Cnd) ||
     # Load/use hazard
     E icode in { IMRMOVQ, IPOPQ } && E dstM in { d srcA, d srcB };
```

Thank You!
